

Unifying lessons from genetically guided drug discovery for neurodegenerative diseases

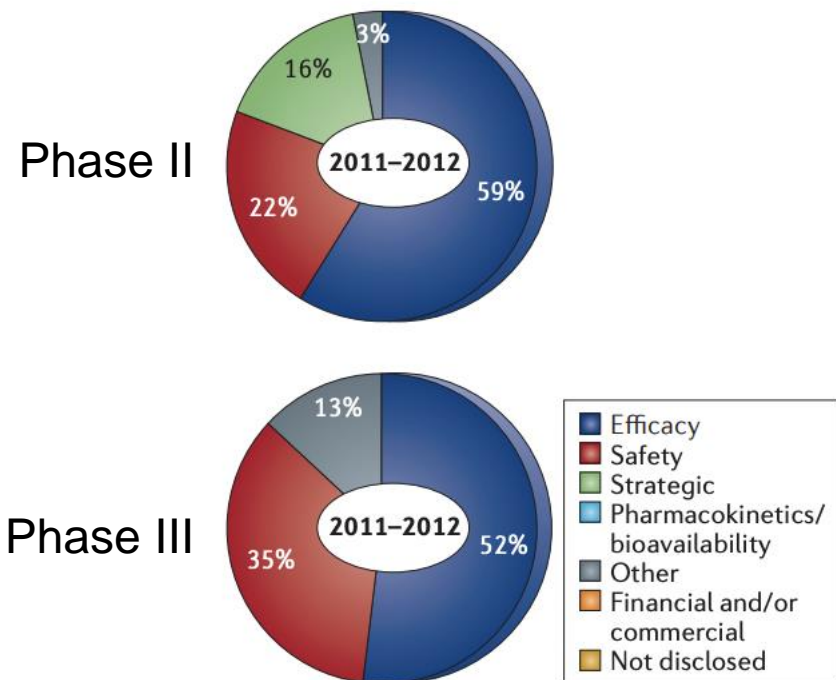

Eric Vallabh Minikel

Broad Institute

November 12, 2024

The problem: most drugs fail

- Overall 8-14% success rate for Phase I to Launch
- Productivity has declined for decades
- Lack of efficacy accounts for much/most failure

Our personal journey

My wife Sonia Vallabh and I learned in 2011 that she had inherited a lethal genetic mutation in *PRNP* from her mother who died of prion disease. We changed careers to become scientists and now run a lab dedicated to developing drugs for prion disease.

Polymorphisms and Variants

Gene/Region	Allele	Frequency	Comment
PrP ^C	129M	0.5	129M/129M
PrP ^C	129V	0.5	129M/129V

Interpretation
 Test results should be interpreted in the context of the patient's clinical presentation and family history.
 A heterozygous c.532 G>A (p.D176N) mutation was detected. In addition, a heterozygous c.129M>V, polymorphism was also detected. This polymorphism results in a 129M/V genotype. The c.532 G>A (p.D176N) mutation is the most common pathogenic mutation in the c.532 G>A (p.D176N) mutation in the PRNP gene. The c.532 G>A (p.D176N) mutation has been reported in patients with genetic prion disease. This result is consistent with the diagnosis of genetic prion disease of this individual.
 Genetic counseling is recommended. Genetic testing is available for at-risk relatives.
Methodology
 Polymerase Chain Reaction (PCR) amplification followed by bi-directional sequence analysis of a DNA sample from this individual was used to analyze the gene encoding the prion protein, PRNP, for changes associated with inherited PRNP disease. Gene bank sequence NC_002111.3 is used as the reference sequence.

The NEW ENGLAND JOURNAL of MEDICINE

The Patient-Scientist's Mandate

Sonia M. Vallabh, Ph.D.

Eight years ago, at the age of 27, I learned that I had inherited a fatal genetic mutation in the prion protein gene (*PRNP*). Pathogenic mutations in this gene questions we fielded from day one: whether it was wise to pursue genetic testing for a currently incurable disease; how we would weather the setbacks inherent in drome, testing drugs in healthy carriers will require a primary prevention strategy based on genetic risk. This realization has defined our priorities for the past

Our personal journey

My wife Sonia Vallabh and I learned in 2011 that she had inherited a lethal genetic mutation in *PRNP* from her mother who died of prion disease. We changed careers to become scientists and now run a lab dedicated to developing drugs for prion disease.

Final Report

Patient Name: VALLABH, SONIA
 Genetic ID #: 11-001889 Type of Specimen: DNA from Blood
 Date of Birth: 2/28/1984 Date of Sample: 10/28/2011
 Institute: MGH/SPC Date Received: 10/28/2011
 Reference ID #: 2011-1775 Final Report: 11/11/2011

Referred by: Pfenning Gaskell, M.D., NDDPSC, SP-007
 Critical Indication: Relative of individual previously to have a mutation
 - The individual has no symptoms at this time
 - Mutation: D178N-L294R

PRION Mutation Screening Results

A heterozygous c.532 C>A (p.D178N) mutation was detected in the PRNP gene. This mutation is associated with sporadic Creutzfeldt-Jakob disease (sCJD) and is also detected in the c.532 C>A (p.D178N) mutation in the PRNP gene. The c.532 C>A (p.D178N) mutation has been reported in patients with genetic prion disease. This result is consistent with the diagnosis of genetic prion disease of this individual.

Gene	Allele	Frequency	Comment
PRNP	c.532 C>A (p.D178N)	0.0001	Pathogenic
PRNP	c.129A>G (p.R42G)	0.0001	Pathogenic
PRNP	c.146G>A (p.E48K)	0.0001	Pathogenic
PRNP	c.146G>T (p.E48V)	0.0001	Pathogenic
PRNP	c.146G>C (p.E48Q)	0.0001	Pathogenic
PRNP	c.146G>T (p.E48V)	0.0001	Pathogenic
PRNP	c.146G>C (p.E48Q)	0.0001	Pathogenic
PRNP	c.146G>T (p.E48V)	0.0001	Pathogenic
PRNP	c.146G>C (p.E48Q)	0.0001	Pathogenic

INTERPRETATION

Test results should be interpreted in the context of the patient's clinical presentation and family history. A heterozygous c.532 C>A (p.D178N) mutation was detected. In addition, a heterozygous c.129A>G (p.R42G) mutation was also detected. This polymorphism results in a 129A>V genotype. The c.129A>V mutation has the 129M polymorphism and the c.532 C>A (p.D178N) mutation in the PRNP gene. The c.129A>V (p.R42G) mutation has been reported in patients with genetic prion disease. This result is consistent with the diagnosis of genetic prion disease of this individual.

Genetic counseling is recommended. Genetic testing is available for at-risk relatives.

METHODS

Polymerase Chain Reaction (PCR) amplification followed by bi-directional sequence analysis of a DNA sample from this individual was used to analyze the gene encoding the prion protein, PRNP, for changes associated with inherited prion disease. Gene bank accession NO: 200111.1 is used in the reference sequence.

Unit of analysis: target-indication pair

Targets – human genes (refers to the gene or gene product)

Indications with "genetic insight" i.e. that have been studied genetically

Calculating probability of success $P(S)$

Phase I

with genetic support

322

succeeded

- entered Phase II

438

target-indication pairs
that entered Phase I,
outcome known:

- entered Phase II+
- terminated
- timed out (presumed abandoned)

Calculating probability of success P(S)

Phase I

with genetic support

$$\frac{322}{438} = 73.5\%$$

Calculating probability of success P(S)

$$\begin{array}{ccc} \text{Phase I} & & \text{Phase II} & & \text{Phase III} \\ \text{with genetic support} & & \text{with genetic support} & & \text{with genetic support} \\ \frac{322}{438} & \times & \frac{191}{390} & \times & \frac{183}{225} & = & 29.3\% \end{array}$$

Calculating relative success (RS)

$$\begin{array}{ccc} \text{Phase I} & \text{Phase II} & \text{Phase III} \\ \text{with genetic support} & \text{with genetic support} & \text{with genetic support} \\ \frac{322}{438} & \times & \frac{191}{390} \times \frac{183}{225} = 29.3\% \end{array}$$

$$\begin{array}{ccc} \text{Phase I} & \text{Phase II} & \text{Phase III} \\ \text{no genetic support} & \text{no genetic support} & \text{no genetic support} \\ \frac{5,490}{8,200} & \times & \frac{2,071}{7,044} \times \frac{1,378}{2,578} = 10.5\% \end{array}$$

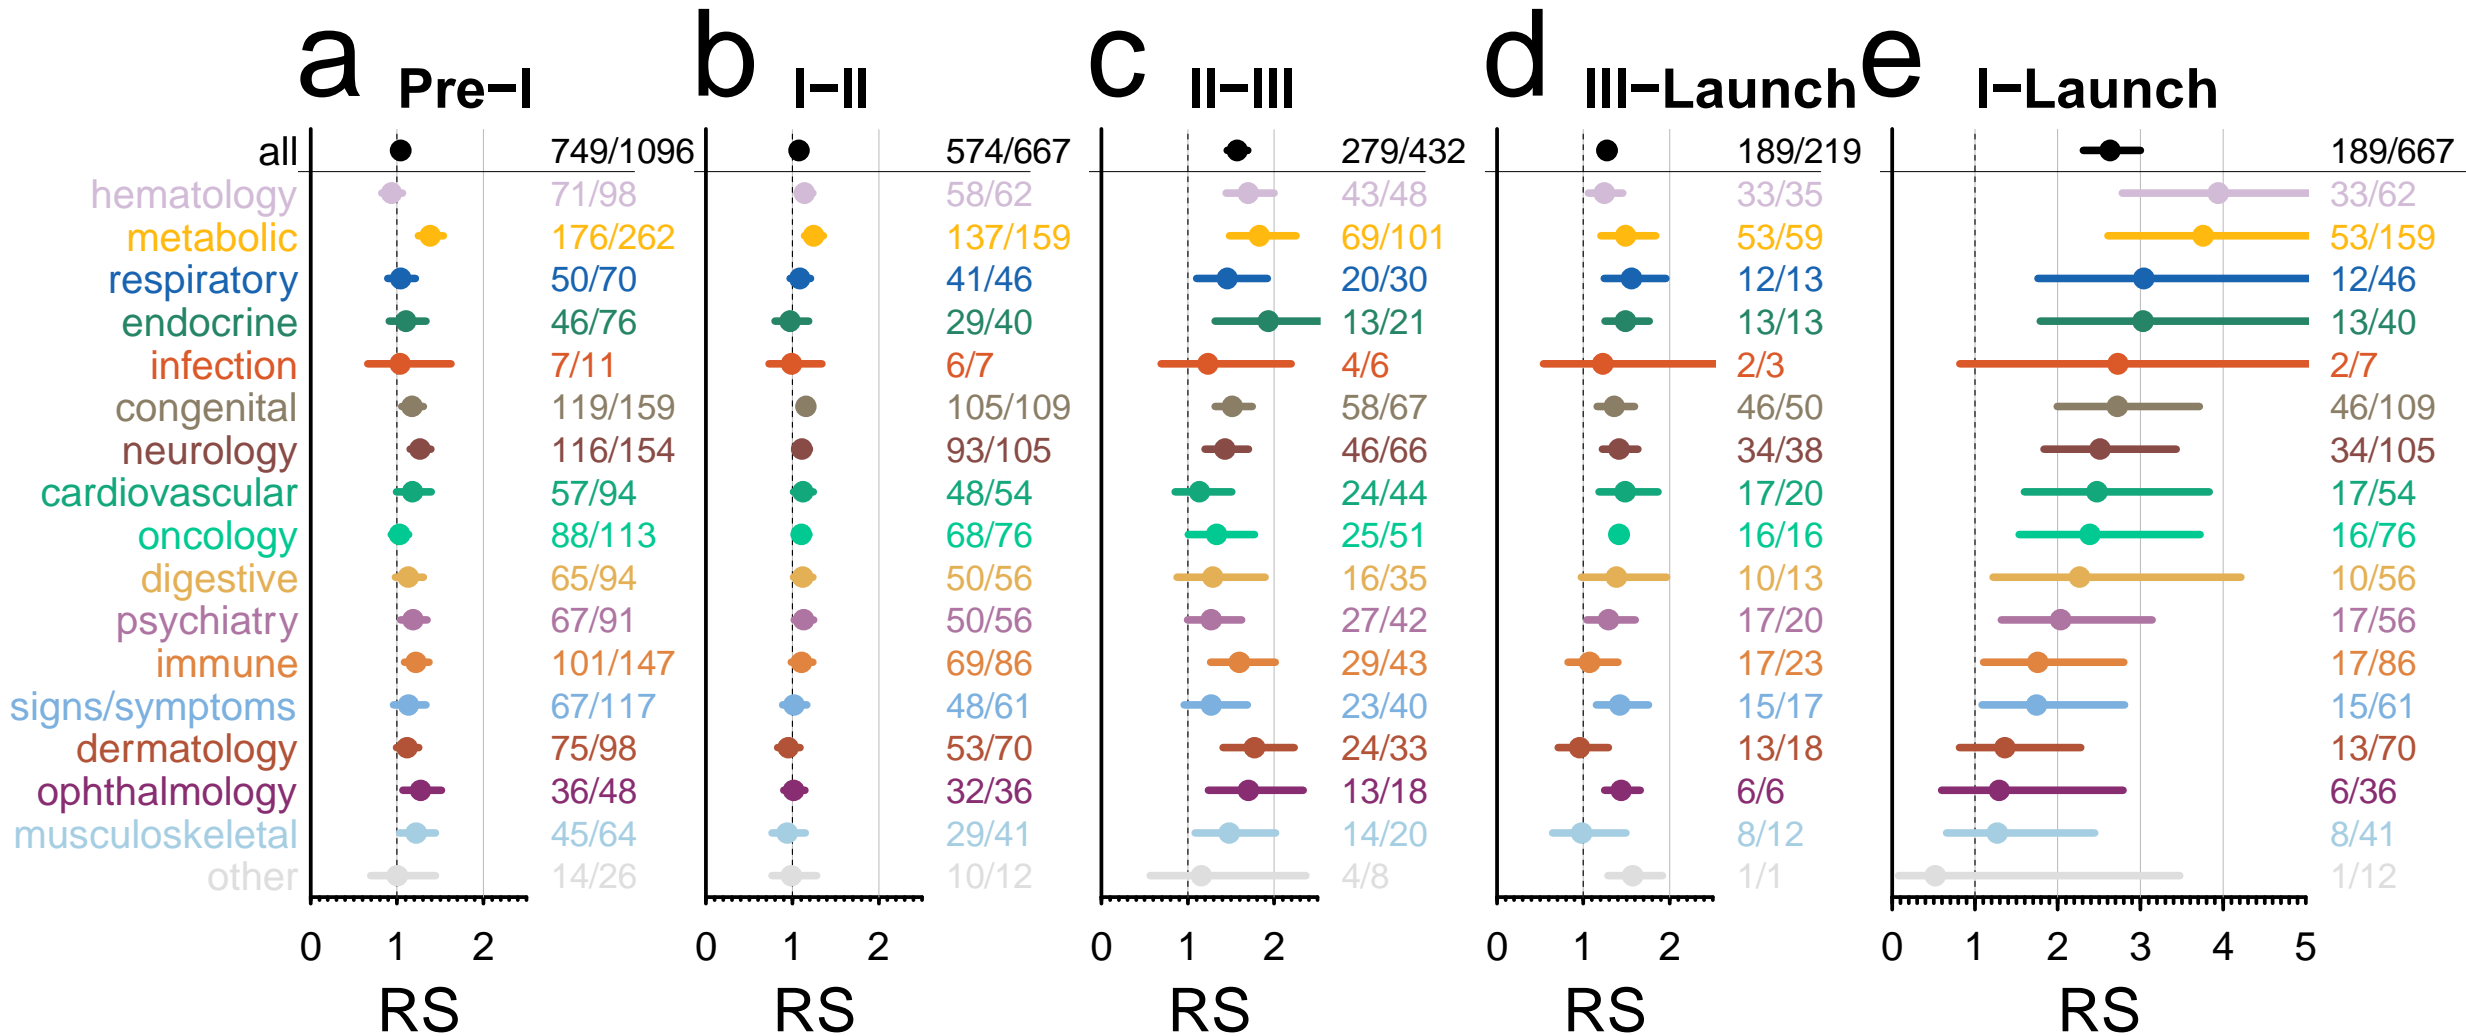

Calculating relative success (RS)

$$\frac{322}{438} \times \frac{191}{390} \times \frac{183}{225}$$

$$= 2.78$$

$$\frac{5,490}{8,200} \times \frac{2,071}{7,044} \times \frac{1,378}{2,578}$$

How does relative success vary by therapy area?

Why does genetic evidence affect different therapy areas differently?

- Matt Nelson's hypothesis:
 1. genetic evidence matters more for **disease-modifying** than **symptom-managing** drugs
 2. different proportions of these types of drugs across therapy areas
- This distinction is not captured in any known database

Why does genetic evidence affect different therapy areas differently?

- In search for proxy variables, I browsed all the approved T-I pairs in neurology...

target	N	approved indications
DRD2	12	alzheimer disease, migraine disorders, parkinson disease, tourette syndrome, hyperprolactinemia, acromegaly, restless legs syndrome, dementia, dementia, vascular, nervous system diseases, dyskinesias, psychomotor agitation
SCN1A	11	epilepsy, neuralgia, trigeminal neuralgia, epilepsy, tonic-clonic, status epilepticus, epilepsies, partial, epilepsy, absence, lennox gastaut syndrome, epilepsies, myoclonic, migraine disorders, epilepsy, generalized
GABRA1	9	sleep initiation and maintenance disorders, epilepsy, generalized, epilepsy, sleep wake disorders, nervous system diseases, spasm, epilepsies, partial, lennox gastaut syndrome, status epilepticus
SLC6A2	9	brain ischemia, stroke, diabetic neuropathies, fibromyalgia, neuralgia, alzheimer disease, cataplexy, narcolepsy, sleep initiation and maintenance disorders
NR3C1	8	pituitary acth hypersecretion, dermatomyositis, multiple sclerosis, optic neuritis, spasms, infantile, polymyositis, muscular dystrophy, duchenne, brain edema
SMN2	1	muscular atrophy, spinal
TLR3	1	fatigue syndrome, chronic
TLR4	1	cerebral infarction
TPP1	1	neuronal ceroid-lipofuscinoses
TTR	1	amyloid neuropathies, familial

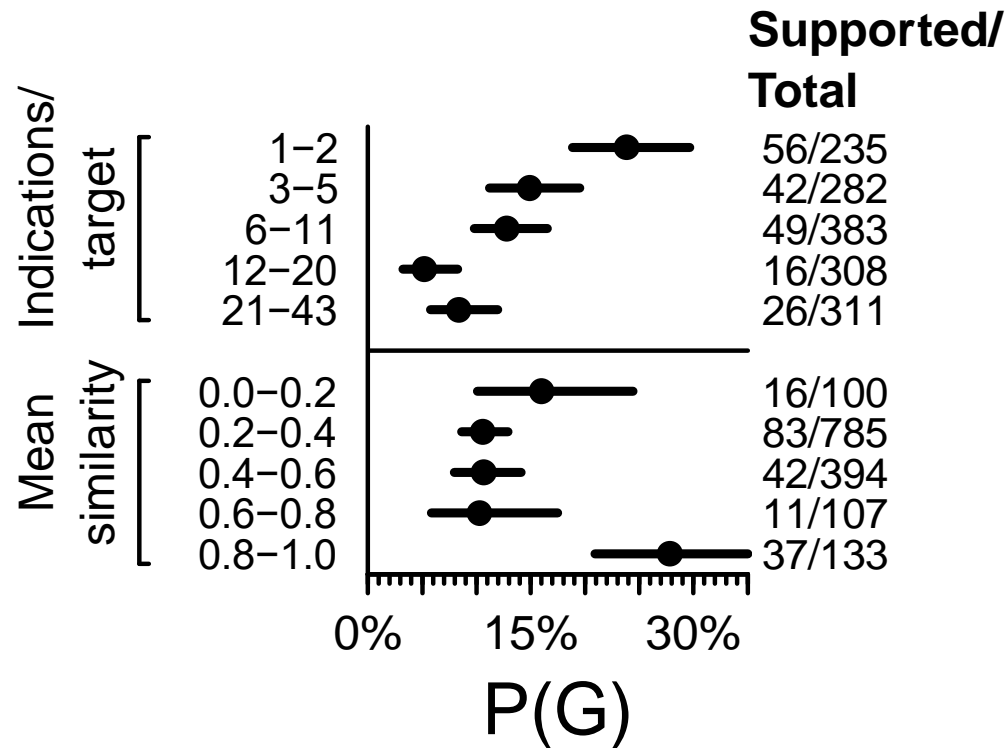

- Hypothesis: symptom-managing drugs tend to be re-used for many diverse indications, while disease-modifying drugs have narrower use in one or a few indications

Targets for *more* indications are also approved for *less similar* indications

- Of 450 targets of approved drugs, 42 with ≥ 10 indications are 39% of approved T-I pairs
 - Examples: corticosteroids, painkillers, anti-inflammatories, anti-muscarinics, anti-dopaminergics, and chemotherapy
- Inverse correlation between number of indications and similarity thereof ($r = -0.72$) — but similarity also provides orthogonal information

Genetic support for approved drugs is enriched for targets with few or highly similar indications

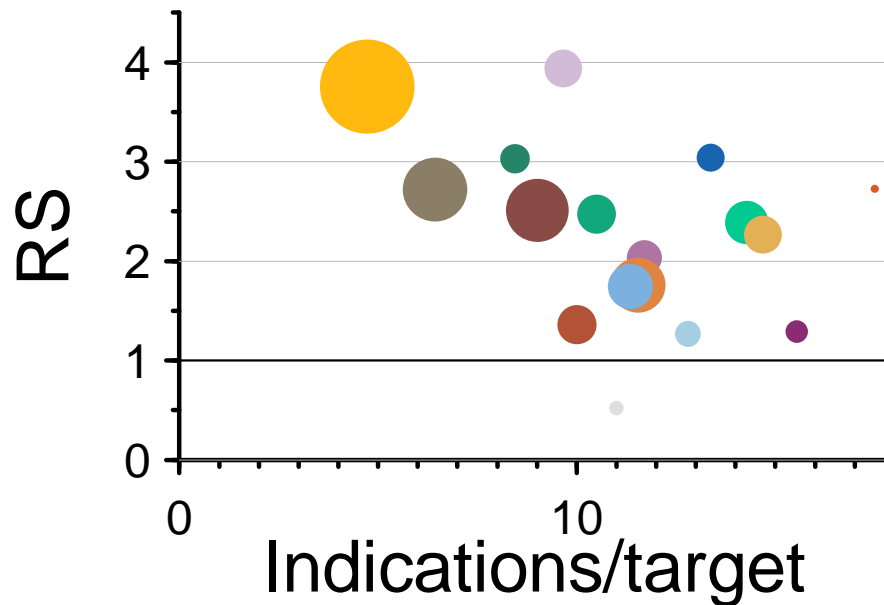

- Group all targets by the count or similarity of approved indications — what proportion of their indications have genetic support?
- Genetic support more common for T-I pairs where the target has fewer or more similar indications

Across therapy areas, number and diversity of indications per target correlates with value of genetic evidence

- Similarity vs. RS: $r = 0.74$, $P = 0.001$

Across therapy areas, number and diversity of indications per target correlates with value of genetic evidence

- Similarity vs. RS: $r = 0.74$, $P = 0.001$
- Indications per target vs. RS: $r = -0.62$, $P = 0.008$

Conclusion/hypothesis: genetic evidence really matters for *disease modification*

- If true:
 - differences between therapy areas simply reflect how much of the portfolio is disease modifying vs. symptom-managing
 - the true value of genetic evidence is even higher than we estimate
- Limitations: all indirect evidence, still no direct “gold standard” to test this

Are GWAS hits just as good as Mendelian targets a priori?

- Remember, this is relative success from Phase I onward
- What about preclinical target selection?
 - 65% of disclosed preclinical programs progress to Phase I — but many failures are never disclosed

Developing a GWAS hit as a drug requires believing that phenotypic impact scales with target engagement

	GWAS hit	Drug
Functional impact (on gene expression or function)	small	large
Phenotypic impact	small	large

Defining relative success versus yield

Type 2 diabetes (T2D) example

	Supported potential targets	Supported successful targets	Supported unsuccessful targets	“Yield”
Mendelian	19	4	0	21%
GWAS	862	7*	7	0.8%

GWAS discoveries are:

- More recent
- Mechanism often not initially clear

But, GWAS hits can also be invalidated in early functional studies...

GPR151 is an example where larger functional effect did *not* yield larger phenotypic impact

Portfolios are not much more enriched for genetic support today than historically

A minority of trials in neurodegenerative diseases are genetically supported...

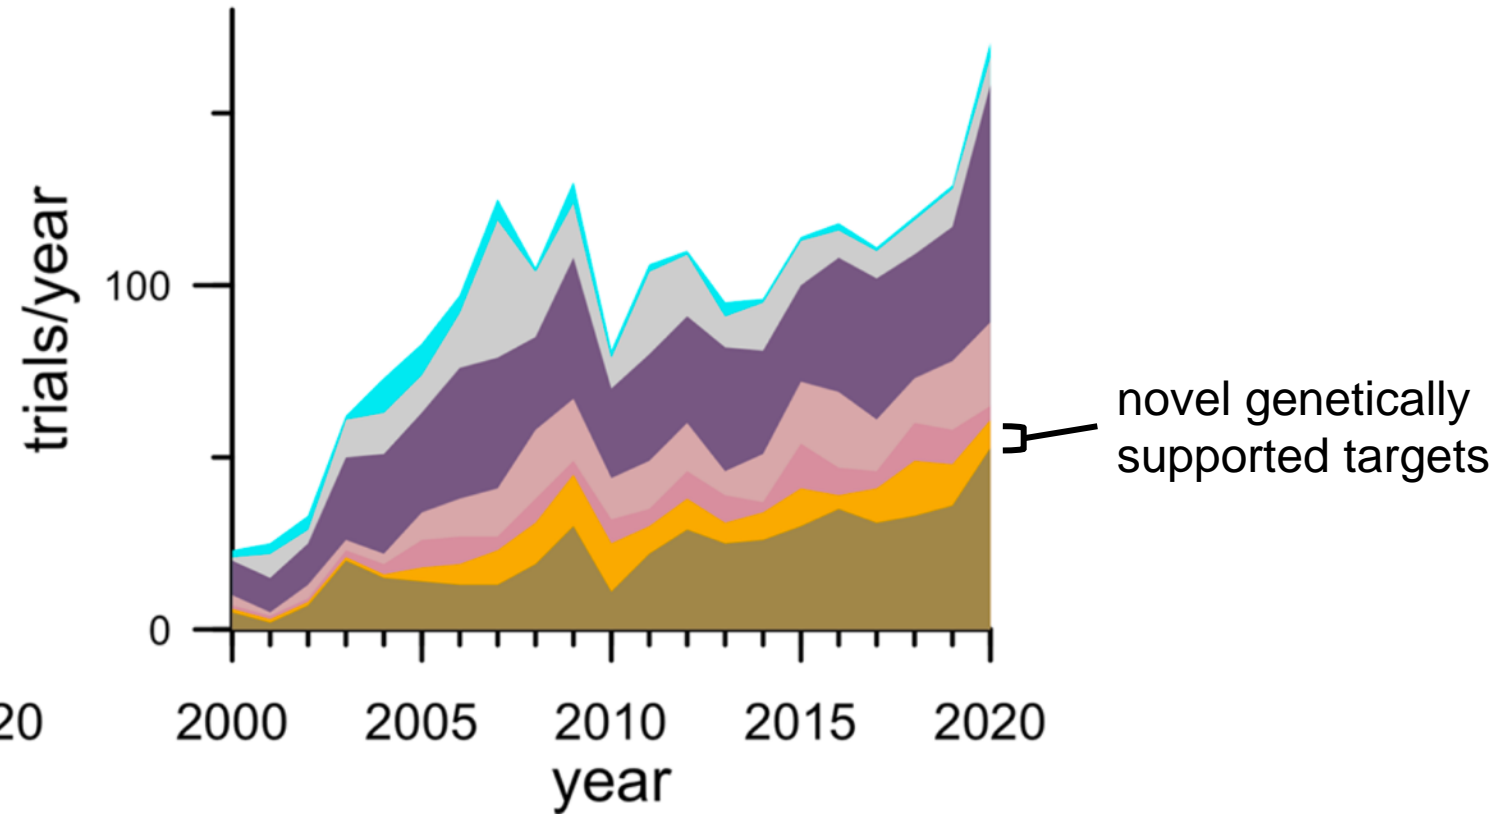

Genetically supported targets account for a small (and non-increasing) minority of all trials in neurodegeneration

And almost all focus is on amyloid beta

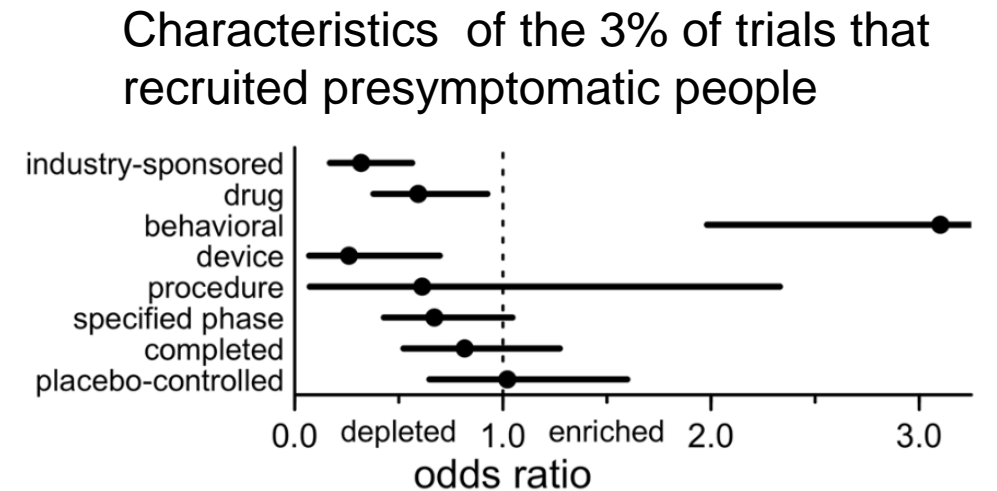

... and that proportion has not risen over time

Potential for misalignment between disease stages in genetic studies and in clinical trials

Disease stage recruited in AD/PD/FTD/ALS/HD trials, 2000-2020

Are the same mechanisms operative in *initiation* and *progression* of disease?

Sometimes **no**:

Genetic Risk for Alzheimer Disease Is Distinct from Genetic Risk for Amyloid Deposition

Our study suggests that *APOE* mostly contributes to amyloid accumulation and the PRS affects risk of further conversion to AD.

Genome-wide association study of rate of cognitive decline in Alzheimer's disease patients identifies novel genes and pathways

Discussion: Pathways related to AD, intelligence, and neurological function determine AD progression, while previously identified AD risk variants, including the apolipoprotein (*APOE*) $\epsilon 4$ and $\epsilon 2$ variants, do not have a major impact.

We also examined the top SNPs in 32 known AD risk genes,⁷⁷⁻⁷⁹ and also the SNPs tagging the *APOE* $\epsilon 2$ and $\epsilon 4$ alleles, for association with ROD. After correcting for the number of SNPs tested, only rs1476679 in zinc finger CW-type and PWWP domain containing 1 (*ZCWPW1*, $p_{LME} = 3.07 \times 10^{-6}$, $p_{GEE} = 3.9 \times 10^{-4}$), was significantly associated with ROD. Notably, the minor allele (C) is protective for AD and associated with slower ROD.⁷⁷ Although the associations were observed with different variants, *CNTNAP2*⁷⁹ and phospholipase C gamma 2 (*PLCG2*)⁸⁰ have also recently been implicated as AD risk genes.

Are the same mechanisms operative in *initiation* and *progression* of disease?

Sometimes **yes**:

- PrP lowering
- HTT somatic instability mitigation
- Amyloid beta clearance

Are the same mechanisms operative in different neurodegenerative diseases?

No correlation between AD and PD genetic risk coefficients, genome-wide

Of curated genetic hits (Mendelian & GWAS) for AD, PD, FTD/ALS, and HD as of 2022, *MAPT* was the **only** overlap for >1 disease

Fig. 2. Genetic correlations across neurological phenotypes. The color of each box indicates the magnitude of the correlation, and the size of the box indicates its significance (LDSC), with significant correlations filling each square completely. Asterisks indicate genetic correlations that are significantly different from zero after Bonferroni correction. Some phenotypes have substantial overlaps (Table 1)—for instance, all cases of generalized epilepsy are also cases of epilepsy. Asterisks indicate significant genetic correlation after multiple testing correction.

“Cross-cutting mechanisms” sounds good, but is it really?

ABOUT US

WHAT WE DO

Ben Barres Early Career Acceleration Awards (Cycles 1- 2)

- Understanding common disease mechanisms that cut across diseases and that may point to common avenues for intervention.

If the drug targets are not the same, then what do Alzheimer's disease, prion disease, etc. have in common?

If the drug targets are not the same, then what do Alzheimer's disease, prion disease, etc. have in common?

- Prion mechanism
 - Seeding assays for diagnosis
 - Strain typing to predict clinical phenotypes
 - Challenge-based animal models
 - Decontamination & transmission concerns
- Neurodegeneration & neuroinflammation
 - NfL, T-tau, GFAP, etc. biomarkers for prognostication & monitoring
- At-risk, prodromal, and manifest disease stages
 - Need for longitudinal observational studies
 - Need for new clinical paths & regulatory flexibility

Common needs for drug discovery

- Platform technologies to target specific genes
- Delivery systems for the human CNS

Holly Kordasiewicz

Ken Chan

11:30a – 12:40p

Thursday 11/14

Rational drug design for prion disease and how this
informs other ADRDs

Platform technologies for targeting specific disease proteins

- DNA-targeted
 - Base editing
 - Epi-editing
 - Transcriptional repressors
- RNA-targeted
 - ASO
 - siRNA
 - ADAR
- Protein-targeted
 - mAbs
 - Secretory inhibitors

Platform technologies for delivery

- Engineered AAVs
- Engineered Fc mAbs
- mAb-RNA conjugates
- Conjugated / chemically stabilized oligonucleotides

Conclusions

- Success is rare in drug discovery, especially neurodegeneration
- Human genetic evidence improves success rate
 - But not all hits are good drug targets
- Consideration regarding disease stage is merited
- Specific targets are rarely shared between diseases
 - And when they are, they still may not be the best targets
- The real opportunity: develop **platforms** and **delivery systems** that cross-cut diseases

Thank you

eminikel@broadinstitute.org
